The screenshot shows the GitHub repository page for `caronc/apprise`. The repository is public and has 4.5k stars, 167 forks, and 46 watchers. It includes a navigation bar with links for Code, Issues (32), Pull requests (5), Actions, Wiki, Security (1), and Insights. The main content area shows the `master` branch with 12 branches and 30 tags. A recent commit by `caronc` titled "FCM Plugin Supports more Payload Options (#489)" is visible, along with a file `.github` and a commit message "Create codeql-analysis.yml". The repository description states: "Apprise - Push Notifications that work with just about every platform!" and provides a link to the Docker Hub repository: hub.docker.com/r/caronc/apprise.

Apprise allows you to send a notification to almost all of the most popular notification services available to us today

What is Apprise?

Apprise is an open source application that allows you to **send push messages to more than 70 services** (Messenger, SMS, Email, Home Assistant, ...) **without having to integrate the individual native APIs of these services on your end.**

Messages can be sent to **multiple messaging services at the same time**, so if a single messaging service fails, the message is still delivered via backup services.

Apprise was written in Python and **can either be used as a standalone program** (command line) **or integrated into existing code** - **there is also a Docker image available.** All service-specific credentials are either stored in Apprise-specific **configuration files** or can be passed to Apprise as parameters. All **credentials are protected** and do not appear in log files.

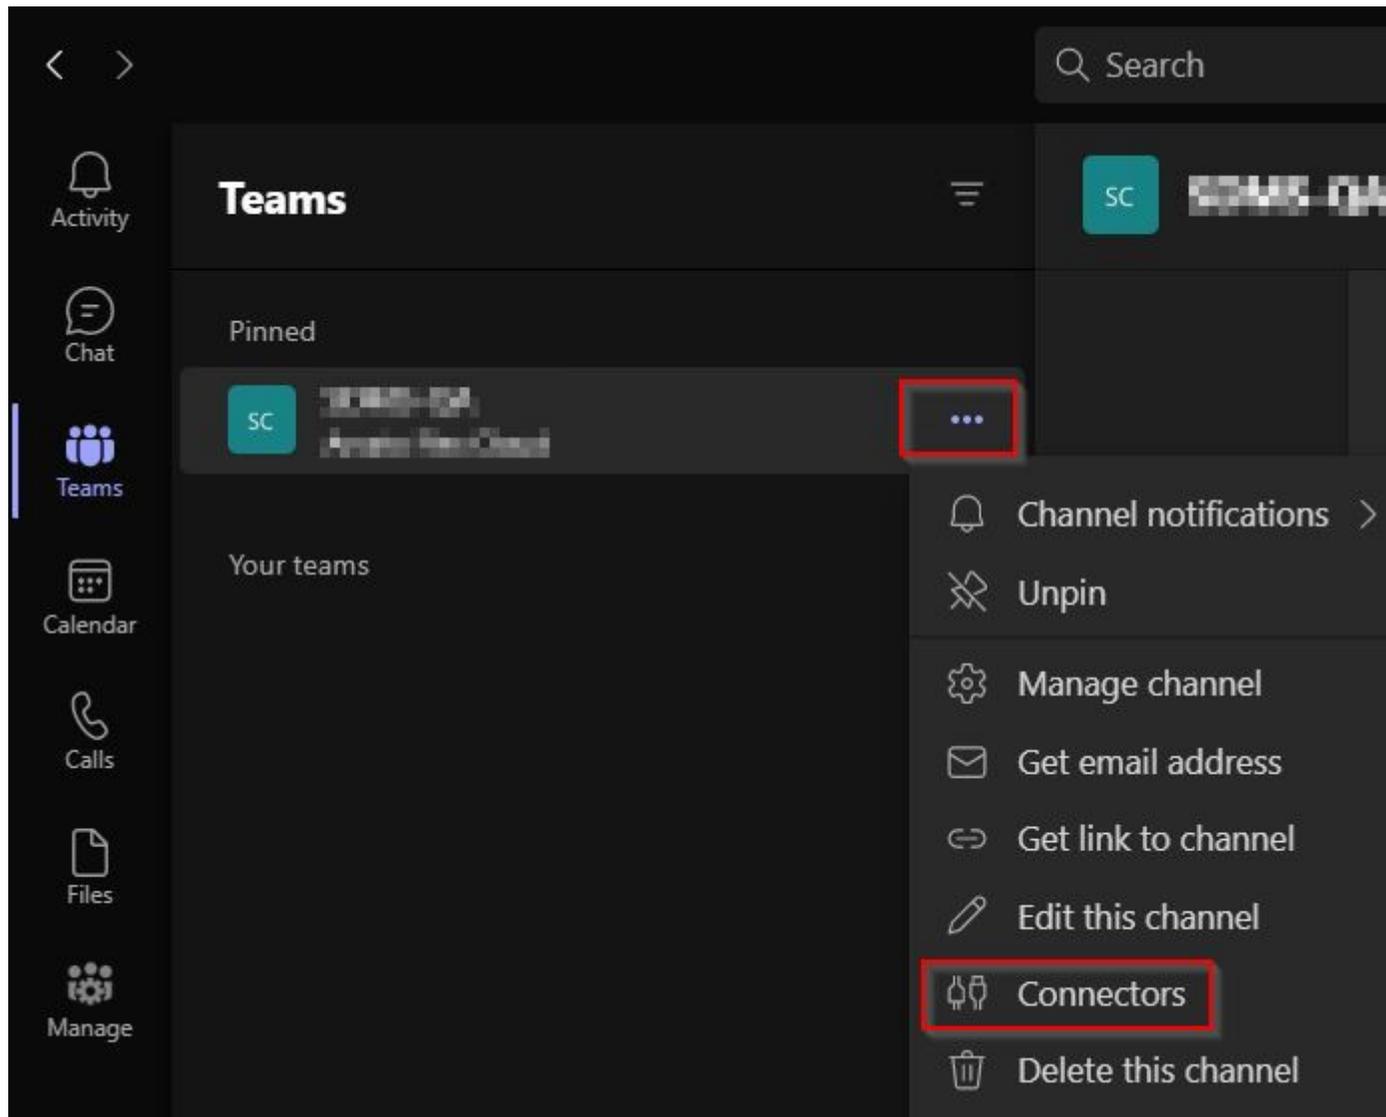

Depending on the capabilities of the messaging service, Apprise **supports HTML and/or text messages.** In addition, **users can send file attachments, such as log files or images**, if supported by the messaging service. To prevent the messaging process from accidentally blocking your code, Apprise **uses asynchronous processing.**

Example configuration of Apprise and a Microsoft Teams channel

In the following example I will create a sample configuration of Apprise for sending a message to a Microsoft Teams channel. Keep in mind that each Apprise-supported messenger service has its own individual configuration documentation, which you can access either via **the main page of the Apprise project** or via **its wiki**. Thus, we first select the **Microsoft Teams configuration documentation for Apprise in the wiki**, where we can get generic information about the plugin's configuration, messaging capabilities, etc.

Creating the Webhook in Microsoft Teams

In order to be able to configure Apprise for Microsoft Teams, we first need to set up a so-called **Incoming Webhook**. This Webhook can be configured in Microsoft Teams, assuming that you are an administrator of the channel in question. To do this, first go to your channel in Microsoft Teams and then click on the three dots behind the name of your channel, and select the menu item **Connectors**.

To create a new Webhook, click the **Incoming Webhook** item's **Configure** button. If you need to edit this webhook later or look up the Webhook's URL again, select **Manage /Configured** instead.

Connectors for "XXXXX" channel in "XXXXX" team ✕

Keep your group current with content and updates from other services.

MANAGE

Configured

My Accounts

Connectors for your team

 **Incoming Webhook** Configure
Send data from a service to your Office 365 group in real time.

The data required for creating a webhook is rather limited. You just have to specify a name and an optional icon for your webhook.

Incoming Webhook

[Send feedback](#)

The Incoming Webhook connector enables external services to notify you about activities that you want to track. To use this connector, you'll need to create certain settings on the other service, which needs to support a webhook that's compatible with the [Office 365 connector format](#).

Fields marked with * are mandatory

To set up an Incoming Webhook, provide a name and select Create. *

Customize the image to associate with the data from this Incoming Webhook.

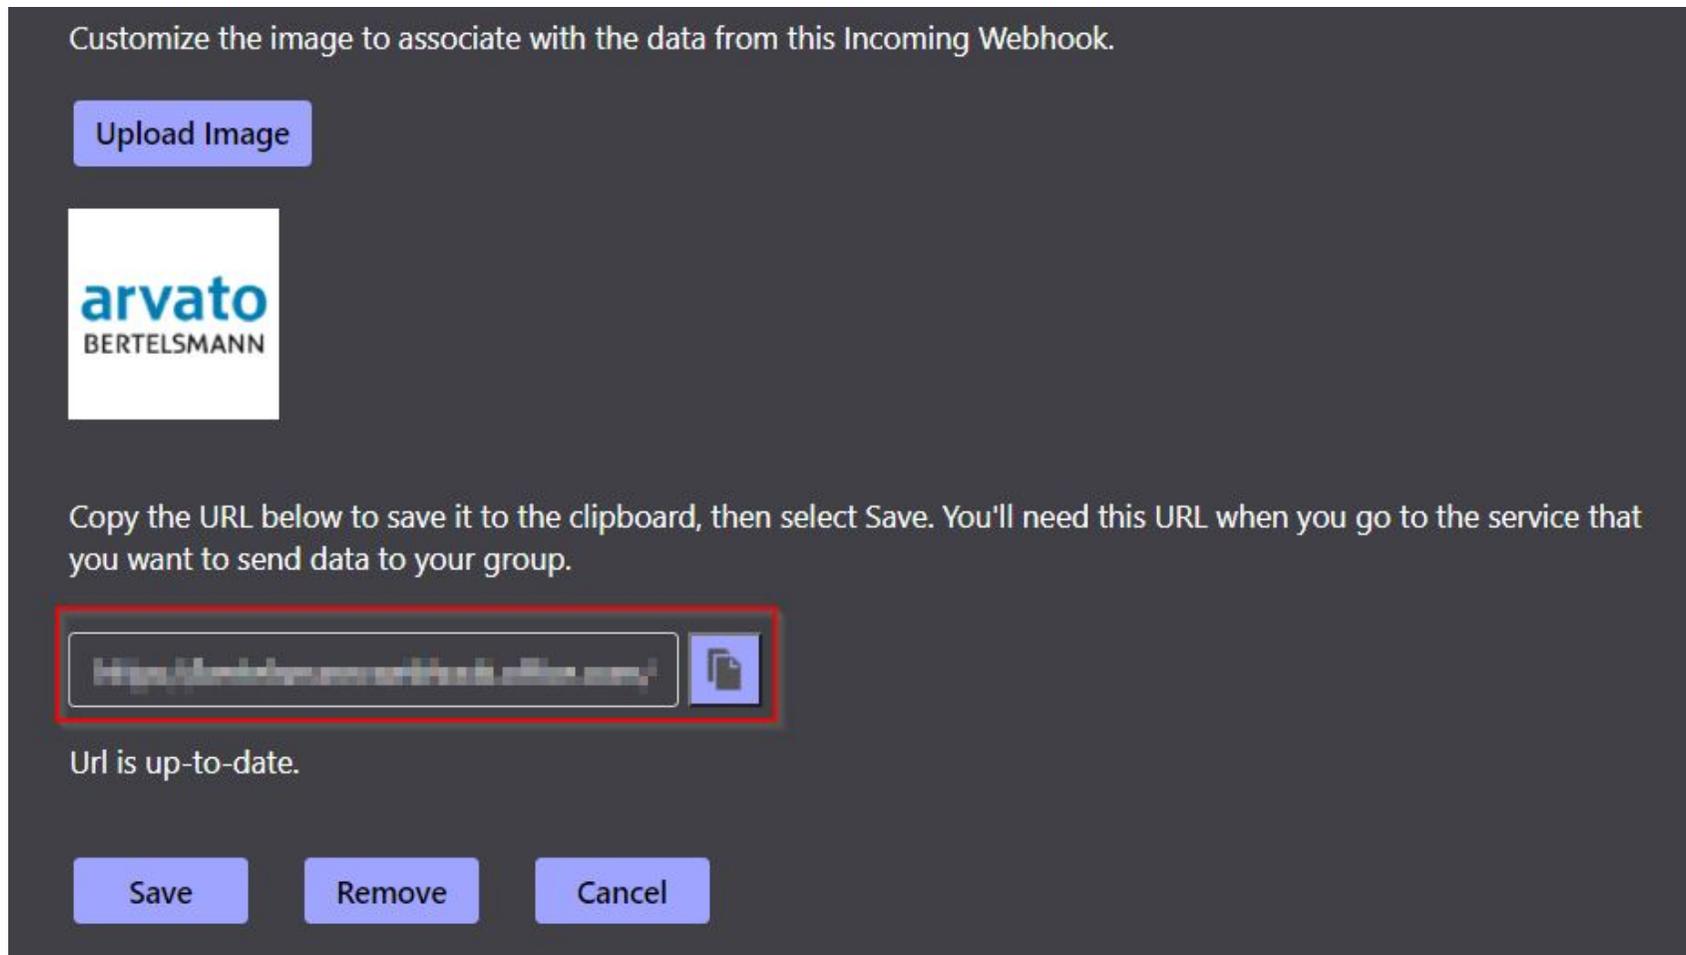

Upload Image

Create

Cancel

Once the webhook is created, create a copy of the link and close this dialog.

Your webhook will look something like this:

```
https://bcp.webhook.office.com/webhookb2/f13637ba-adcb-4312-8966-a1b2c3ddefd8@d8aa127b-66d4-4ff2-1234-abbf1234daab/IncomingWebhook/09abdfba21b046d7a172d5133199293f/9b22a5e7-7dda-4bb3-1317-82b13e9ff09
```

We now need to convert this webhook into the Apprise-specific format so that it can be used by Apprise's Microsoft Teams plugin. To do this, [we follow the plugin's wiki documentation](#).

The resulting link looks like this:

```
msteams://bcp/f13637ba-adcb-4312-8966-a1b2c3ddefd8@d8aa127b-66d4-4ff2-1234-  
abbf1234daab/09abdfba21b046d7a172d5133199293f/9b22a5e7-7dda-4bb3-1317-82b13e9ff09
```

Time for a test run!

Now that we've finished configuring the Apprise plugin, we can finally send a message to our Microsoft Teams channel. To do this, we pass a *message body* as well as an optional *message title* to Apprise in addition to the configuration we just created:

```
apprise -t "Hello BCP Community" -b "Apprise messaging test";  
msteams://bcp/f13637ba-adcb-4312-8966-a1b2c3ddefd8@d8aa127b-66d4-4ff2-1234-  
abbf1234daab/09abdfba21b046d7a172d5133199293f/9b22a5e7-7dda-4bb3-1317-82b13e9ff09
```

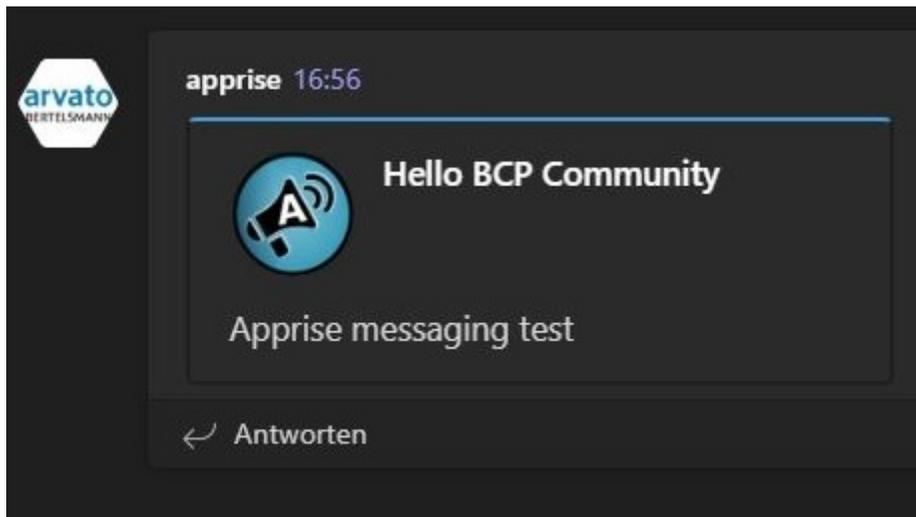

In the following example, I use PyCharm to call the Apprise application/API, but this call could just as easily have been made via command line or else by calling Apprise as a library from your code.

The screenshot shows the Visual Studio Code interface with the Run and Debug console open. The console displays the following command and output:

```
C:\Users\scult16\mygit\apprise\venv\Scripts\python.exe C:/Users/scult16/mygit/apprise/bin/apprise -t "Hello BCP Community" -b "Apprise messa  
Process finished with exit code 0
```

The command is highlighted with a red box. The output shows that the process finished successfully with an exit code of 0. The status bar at the bottom indicates the current environment is Python 3.8 (apprise) on the master branch.

In case of success, Apprise should then return a return code of 0 and the message should be visible in your Microsoft Teams channel.

Create your own Messenger plugin

If your favorite messenger service is not available in Apprise, it is easy to implement new plugins, provided of course that your messenger service offers an appropriate API.

Preferably, check if an existing Apprise plugin service matches your messenger's feature set in message format and parameters and then use this plugin as a template for your new messenger service. Alternatively, you can take a look at the [developer wiki](#), where the basics of creating your own plugin are discussed.

For the creation of the actual plugin the following files / directories might be relevant:

- The `apprise/apprise/plugins` directory. This is where you keep your messenger plugin. You will also find all existing plugins in this directory.
- The file `apprise/apprise/utils.py` defines regular expressions that are used to validate the input parameters of your later plugin. Normally you will not have to make any changes here.
- Additionally, you should provide a test of your plugin under `apprise/tests`.

Please note that your plugin code must provide Python2 backwards compatibility; this requirement will be enforced as part of the pull request's validation process.

Finally, when creating new plugins, I always recommend to provide a corresponding wiki page, which shows how the plugin can be used and which restrictions like text format and length it has.

Questions / Comments

If you are interested in creating your own plugin and contributing to Apprise's code base, feel free to drop me a line, check out [my contribution to Apprise's codebase](#), or get in touch with Apprise's core developer [Chris](#).
